

Nematic fluctuations and Raman resonance in iron-based superconductors

Y. Gallais (Université Paris Diderot)

The spontaneous appearance of nematicity, a state of matter that breaks rotation but not translation symmetry, is ubiquitous in many iron based superconductors (Fe SC), and has relevance for the cuprates as well [1,2].

Here I will review recent electronic Raman scattering experiments which report the presence of critical nematic fluctuation in the charge channel in the tetragonal phase of several Fe SC systems. In electron doped Co-BaFe₂As₂ (Co-Ba122), these fluctuations extend over most of the superconducting dome. Their associated nematic susceptibility shows Curie-Weiss behavior, and its doping dependence suggests the presence of a nematic quantum critical point near optimal T_c [3,4] Similar nematic fluctuations are also observed in FeSe despite the absence of magnetic order, raising the question of the link between nematicity and magnetism in FeSC [5].

In the superconducting state of Co-Ba122, I will show that a resonance emerges in the Raman spectra near the nematic quantum critical point. This nematic resonance is a clear fingerprint of the coupling between nematic fluctuations and Bogoliubov quasiparticles, and can be thought as the nematic counterpart of the spin resonance observed in neutron scattering experiments [6].
